The Mid-Level Software Engineer role at Steelcut Software centers on a mission-critical application backed by research-grade machine learning. That is the work I already do. Your site states the production rule I worked under at Oracle Cloud. It favors the smallest, fastest, least complex algorithm with good results. It also calls for versioning, performance metrics, and a plan for retraining.

I worked on the compute host repair service. It recovered 3% of previously unprovisionable bare metal hosts. I built an error spike detector for that service. It watched incoming issues across more than 25 regions. Critical issue detection fell from 8 hours to 20 minutes. I also built CI/CD with automated canary testing. Post-deployment bug realization time fell from 48 hours to 6 hours. The automation saved over 400 developer hours in six months. As an intern I wrote a recursive Java parser for Oracle Digital Assistant REST APIs. It generated more than 1400 test cases. It found 12 critical bugs before release.

I am a master's student and research assistant at Johns Hopkins in Baltimore. I am building a video language alignment framework for surgical video. I designed Circlage, a platform on Azure. It hosts the lab's analysis models for more than 30 surgeons. A model in a notebook is not the same thing as a model other people depend on. I want to keep doing the second kind of work.

GWT is new to me. I tend to treat a new problem as a known one in a different setting. Java services, Linux, bash, tests, and delivery pipelines are the known part. I would use them to maintain the current client components. I would use them on the migration to React.

Bethesda is close to the Johns Hopkins campus. Occasional in-person meetings are realistic from there. I would like to talk about the anchor client's applications.
